## Report

# Determination of the radon diffusion coefficient and radon transfer 

Material/Product

Applicant

weber.tec Superflex 2K thickness $\mathbf{4 , 0} \mathbf{~ m m}$<br>Saint Gobain Weber GmbH<br>Schanzenstraße 84, 40549 Düsseldorf

## Test results

Diffusion coefficient
$\mathrm{D}=1,93 \cdot 10^{-12} \mathrm{~m}^{2} / \mathrm{s}$.
Radon transfer

$$
\Phi_{\text {diff }}=\mathbf{0 , 1 1} \mathbf{B q} /\left(\mathbf{m}^{2} \mathbf{h}\right) \quad \text { at } 100 \mathrm{kBq} / \mathrm{m}^{3} \text { source strength }
$$

## Terms of use

The material can reduce the transfer of radon very good at a thickness of the material of $4,0 \mathrm{~mm}$.
The radon transfer is negligible at a source strength up to $100 \mathrm{kBq} / \mathrm{m}^{3}$. In connection with another protective components (in the floor construction, wall construction) it is good suited to ensure safe radon protection for buildings. This should be based on the actual radon concentration in the soil ${ }^{1}$, which is to be determined on the basis of the radon concentration in $\mathrm{Bq} /(\mathrm{kgh})$.
Details of the measuring device and the measured values are included in the test report from 11.02.2017.

This report is valid for five years. It is to be updated, as soon as the recipe or the properties in relation of the given sample is seemingly only slightly has been changed.

[^0]
[^0]:    ${ }^{1}$ The determination by drilling into the soil and evacuation of the air usually leads to strongly influenced and thus unusable values of the radon concentration. Note: Any radon map of Germany is not suitable to derive statements about the local radon load of the soil for a building, it was created for other purposes.
